

During my analysis of the following data set, all the data types that I was able to identify had some kind of significance. The data types that are used for the table are a mix of both numerals, strings, and dates. I do not see the exact significance of the “Date Added” and “Last Modified,” but all the other columns have significant information. “Nutrient Code,” helps with organizing all of the different kinds of nutrients, “Nutrient Description” describes what each nutrient is, “Nutrient Description Abbrev” gives a short form version of each nutrient, and “Nutrient unit” gives the measurement unit that would be used for each nutrient.

When looking into the relevance and relationships between all the different attributes of the data set, I would say that every piece of data has an implied relationship of some kind. The first four columns are all connected by their identifications classifying each other. For example, the protein nutrient has the nutrient code that makes it simpler to search for them. The abbreviation provides a short form way to identify protein in a nutritional report, and the measurement unit gives what the protein should be measured in in reports. The only columns of data that I am not sure of would be the two columns on the right that display the data the data was added and the last date it was modified. While these could be important in some sense, I do not see it being valuable for creating nutritional plans.

I did not see too many data quality issues in the data set. I am not sure if it was intentional or not, but I was confused about the nutrition codes having gaps in between their numbering. If it were not intentional, having the full set of numberings would be more useful for making nutritional reports. Other than this, I did not see any other issues in this data set. I can see this problem being an issue for problem solving issues using the data. If someone trying to make a report enters a number for the nutritional code that is between two code values, it will return a

missing value or an error that does not allow the receiver to search what the code means because it is not in the graph.

When looking into the given problem for this assignment, I can say that the data given does align with solving the issue of creating nutritional plans for children. Based on a child's health record, the person making the plan can determine what nutrients they need whether that is increasing a child's iron intake or decreasing the amount of sugar a child consumes. Knowing this, a child can be recommended to eat more red meat and eating less surgery snacks throughout the day.
